

A Software Solution can be built
independently in pieces and assembled
to form one big complex application.
The roadmap to this goal sits
underneath.

Micro Services

Problem Statement

The individual track project is a web application that has several components and sub-components that work together and can be developed separately and independently to achieve maintainability and scalability for the software.

Main Question

How to apply micro services to my software solution to achieve the best software architecture design.

Sub Questions

1. Why is it important to break down a software solution into independent components?
2. Why does Microservice Architecture Design help achieve software scalability and maintainability?
3. How does Microservice Architecture Design help achieve software scalability and maintainability?

Chosen Methods to Answer the Main Question

In order to answer the main question, the sub questions need to be answered.

Sub Question 1:

1. Why is it important to break down a software solution into independent components?

To answer this question, I will make use of Decomposition in the Workshop method because it describes and explains the importance of breaking down a complex IT system into smaller parts.

Sub Question 2:

2. Why does Microservice Architecture Design help achieve software scalability and maintainability?

The chosen methods to answer this question are Decomposition in Workshop and Design Pattern Research in Library

Decomposition describes the importance of breaking down an IT system into smaller parts.

And, Design Pattern Research shows that applying the design patterns help improving the quality of an IT system.

Sub Question 3:

3. How does Microservice Architecture Design help achieve software scalability and maintainability?

For this question, the chosen methods are Decomposition in Workshop, Design Pattern Research and available Product Analysis in Library.

The third technique (available Product Analysis) is chosen to read about the process adopted in the development of a complex IT system to learn about and make use of the previous experiences and outcomes for the built of a software solution.

Results

1. Why is it important to break down a software solution into independent components?

The importance of “Breaking a complex IT system or problem into smaller parts ensures its maintainability and robustness, and facilitates cooperation in large-scale software projects.”

Link: [Decomposition - ICT research methods](#)

2. Why does Microservice Architecture Design help achieve software scalability and maintainability?

Microservice Architecture Design helps applying the design principles which “improves the quality (and structure) of the designed software.”

Link: [Design pattern research - ICT research methods](#)

3. How does Microservice Architecture Design help achieve software scalability and maintainability?

As mentioned above Microservice Architecture Design help solve a lot of performance issues and achieve maintainability and scalability by splitting complex systems into smaller reusable and maintainable components starting from separating for example a web app into a frontend and backend and have the latter split into more small components (layers) that communicate between each other and deliver resources after treatment to the frontend using API services.

The question now is the how and the process, which can be answered by identifying “existing solutions” and “embed their work” into mine.

Conclusion & recommendation

The answer to the main question about how to apply Micro Services to my project is to make sure to apply all the design principles (SOLID) and DRY principle and by also making sure that all the components are independent and reusable.

This will help creating a maintainable and scalable application and also will help developing a performing software solution with replaceable components that can be plugged/unplugged easily without causing production break or time consumption.
